(57) **ABSTRACT**

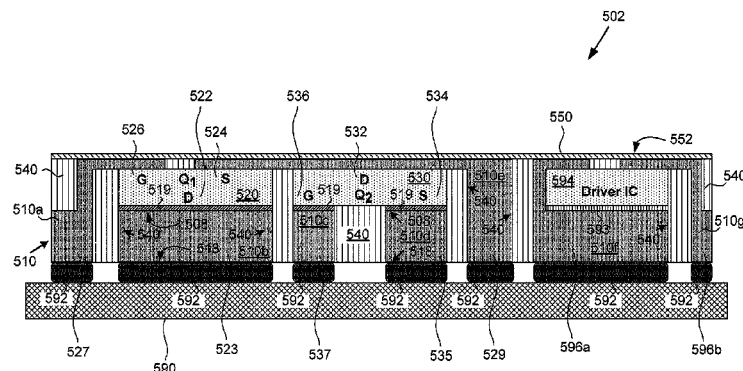

In one implementation, a power semiconductor package includes a non-contiguous, multi-section conductive carrier. A control transistor with a control transistor terminal is coupled to a first section of the multi-section conductive carrier, while a sync transistor with a sync transistor terminal is coupled to a second section of the multi-section conductive carrier. The first and second sections of the multi-section conductive carrier sink heat generated by the control and sync transistors. The first and second sections of the multi-section conductive carrier are electrically connected only through a mounting surface attached to the power semiconductor package. Another implementation of the power semiconductor package includes a driver IC coupled to a third section of the multi-section conductive carrier. A method for fabricating the power semiconductor package is also disclosed. The power semiconductor package according to the present disclosure results in effective thermal protection, current carrying capability, and a relatively small size.

POWER SEMICONDUCTOR PACKAGE WITH NON-CONTIGUOUS, MULTI-SECTION CONDUCTIVE CARRIER

The present application claims the benefit of and priority to a provisional application entitled "Semiconductor Package Including A Conductive Carrier Embedded Power Switching Stage," Ser. No. 61/901,987 filed on Nov. 8, 2013. The disclosure in this provisional application is hereby incorporated fully by reference into the present application.

The present application is also continuation-in-part of application Ser. No. 14/022,584, filed on Sep. 10, 2013, which in turn claims priority to provisional application Ser. No. 61/715,737, filed on Oct. 18, 2012. The disclosures in these applications are hereby incorporated fully by reference into the present application. The present application claims priority to these earlier filed applications.

BACKGROUND

Background Art

Semiconductor packages used in power applications employ power transistors, and are required to operate under high voltage and potentially high temperature conditions. For example, power transistors in voltage converters, sometimes referred to as control and sync transistors, generate substantial heat during operation. The potentially damaging heat can be diverted away from control and sync transistors using a heat spreader, which is often relatively large. In addition, the connection between the control transistor and the sync transistor provides a switch node and is typically implemented using a conductive clip, such as a copper clip, which must be sufficiently robust to accommodate high current. Moreover, because the control and sync transistors can be very sensitive to electrical resistance, the cross-sectional area of the conductive clip used to provide the switch node need be relatively large.

Consequently, packages in power applications, such as voltage converter power semiconductor packages, must typically be sized to accommodate not only control and sync transistors, but a large heat spreader providing thermal protection for those power transistors, and a large conductive clip for their connection, as well. Using heat spreaders and conductive clips require much additional space, and significantly increase the size of power semiconductor packages.

SUMMARY

The present disclosure is directed to a power semiconductor package with non-contiguous, multi-section conductive carrier, substantially as shown in and/or described in connection with at least one of the figures, and as set forth more completely in the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows a diagram of an exemplary circuit suitable for use as a voltage converter.

FIG. 2 shows an exemplary representation of a packaging solution according to one implementation of the present disclosure.

FIG. 3 shows a flowchart presenting an exemplary method for fabricating a semiconductor package according to one implementation of the present disclosure.

2

FIG. 4A illustrates a result of performing of an initial action according to the flowchart of FIG. 3 in accordance with one implementation of the present disclosure.

FIG. 4B illustrates a result of performing of a subsequent action according to the flowchart of FIG. 3 in accordance with one implementation of the present disclosure.

FIG. 4C illustrates a result of performing of a subsequent action according to the flowchart of FIG. 3 in accordance with one implementation of the present disclosure.

FIG. 4D illustrates a result of performing of a subsequent action according to the flowchart of FIG. 3 in accordance with one implementation of the present disclosure.

FIG. 4E illustrates a result of performing of a subsequent action according to the flowchart of FIG. 3 in accordance with one implementation of the present disclosure.

FIG. 4F illustrates a result of performing of a final action according to the flowchart of FIG. 3 in accordance with one implementation of the present disclosure.

FIG. 5 shows an exemplary representation of a packaging solution according to another implementation of the present disclosure.

DETAILED DESCRIPTION

The following description contains specific information pertaining to implementations in the present disclosure. One skilled in the art will recognize that the present disclosure may be implemented in a manner different from that specifically discussed herein. The drawings in the present application and their accompanying detailed description are directed to merely exemplary implementations. Unless noted otherwise, like or corresponding elements among the figures may be indicated by like or corresponding reference numerals. Moreover, the drawings and illustrations in the present application are generally not to scale, and are not intended to correspond to actual relative dimensions.

Power converters, such as voltage regulators, are used in a variety of electronic circuits and systems. For instance, integrated circuit (IC) applications may require conversion of a direct current (DC) input to a lower, or higher, DC output. As a specific example, a buck converter may be implemented as a voltage regulator to convert a higher voltage DC input to a lower voltage DC output for use in low voltage applications in which relatively large output currents are required.

FIG. 1 shows a diagram of an exemplary circuit suitable for use as a voltage converter. Voltage converter 100 includes voltage converter multi-chip module (MCM) 102, output inductor 104, and output capacitor 106. As shown in FIG. 1, MCM 102 includes power switching stage 101 of voltage converter 100, and driver IC 194 implemented to provide drive signals to power switching stage 101. As shown in FIG. 1, voltage converter 100 is configured to receive an input voltage V_{IN} , and to provide a converted voltage, e.g., a rectified and/or stepped down voltage, as V_{OUT} at output 105.

Power switching stage 101 may be implemented using two power switches in the form of metal-oxide-semiconductor field-effect transistors (MOSFETs) configured as a half bridge, for example. That is to say, power switching stage 101 may include high side or control switch 120 (Q_1) having drain 122, source 124, and gate 126, as well as low side or sync switch 130 (Q_2) having drain 132, source 134, and gate 136. Control switch 120 is coupled to sync switch 130 at switch node 129, which, in turn, is coupled to output 105 through output inductor 104. Respective control and sync switches 120 and 130 may be implemented as group IV based power transistors, such as silicon power MOSFETs having a vertical design, for example. Voltage converter 100 may be advanta-

geously utilized, for example as a buck converter, in a variety of automotive, industrial, appliance, and lighting applications.

It is noted that in the interests of ease and conciseness of description, the present inventive principles will in some instances be described by reference to specific implementations of a buck converter including one or more silicon based power FETs. However, it is emphasized that such implementations are merely exemplary, and the inventive principles disclosed herein are broadly applicable to a wide range of applications, including buck and boost converters, implemented using other group IV material based, or group III-V semiconductor based, power transistors. It is noted that as used herein, the phrase “group III-V” refers to a compound semiconductor including at least one group III element and at least one group V element. By way of example, a group III-V semiconductor may take the form of a III-Nitride semiconductor that includes nitrogen and at least one group III element. For instance, a III-Nitride power transistor may be fabricated using gallium nitride (GaN), in which the group III element or elements include some or a substantial amount of gallium, but may also include other group III elements in addition to gallium.

Power switches such as control and sync switches **120** and **130** are capable of generating substantial heat during operation. The potentially damaging heat can be diverted away from control and sync switches **120** and **130** using a heat spreader, which is often relatively large. In addition, the connection between control switch **120** and sync switch **130** providing switch node **129** is typically implemented using a conductive clip, such as a copper clip, which must be sufficiently robust to accommodate high current. Moreover, because control switch **120** and sync switch **130** can be highly sensitive to electrical resistance, the cross-sectional area of the conductive clip used to provide switch node **129** may also be relatively large. Consequently, packaging solutions for power switching stage **101** and/or MCM **102** must typically be sized to accommodate not only control and sync switches **120** and **130**, but a large heat spreader providing thermal protection for those power switches, and a large conductive clip for their connection, as well.

The present application discloses a packaging solution enabling omission of the aforementioned heat spreader and switch node conductive clip, while concurrently providing thermal protection for control and sync switches **120** and **130**, and also providing a reliable, low resistance, and substantially parasitic free electrical connection for establishing switch node **129**. In one implementation, power switching stage **101** is embedded in a conductive carrier utilized as a structural support in the packaging solution, such as a conductive lead frame for example, which is configured to provide integrated heat spreading. In addition, the support structure used to provide the conductive carrier can also be used to provide switch node **129**. FIG. 2 shows an exemplary representation of a packaging solution according to one implementation of the present disclosure.

FIG. 2 shows a cross-sectional view of semiconductor package **201** attached to mounting surface **290**, which may be a printed circuit board (PCB) for example, by solder bodies **292**. Semiconductor package **201** includes fully patterned or multi-section conductive carrier **210**, which itself includes conductive carrier sections **210a**, **210b**, **210c**, **210d**, and **210e** (hereinafter “conductive carrier sections **210a-210e**”). As shown in FIG. 2, the fully patterned or multi-section conductive carrier **210** is a non-contiguous conductive carrier, and is made up of patterned and disjointed sections that are housed within semiconductor package **201**, and that are in electrical

communication only through mounting surface **290**. As shown in FIG. 2, conductive carrier **210** has die side **208**, and opposite input/output (I/O) side **218** connecting semiconductor package **201** to mounting surface **290**. The non-contiguous, fully patterned or multi-section conductive carrier **210**, is also referred to simply as “conductive carrier” in the present application.

Semiconductor package **201** further includes control FET **220** (Q_1) having drain **222**, source **224**, and gate **226**, as well as sync FET **230** (Q_2) having drain **232**, source **234**, and gate **236**. Control FET **220** and sync FET **230** are specific examples of power transistors used for illustrative purposes in the present application. However, it is manifest that other types of power transistors can be used as well without departing from the scope of the present inventive concepts. Thus, control FET **220** may be referred to as control transistor and sync FET **230** may be referred to as sync transistor in the present application. Source, drain, and gate of either control FET and/or sync FET may be referred to as a transistor terminal. A control transistor terminal may refer to source, drain, or gate of the control transistor, i.e. control FET **220** in the present example. Likewise, a sync transistor terminal may refer to source, drain, or gate of the sync transistor, i.e. sync FET **230** in the present example. Moreover, semiconductor package **201** may be referred to as a “power semiconductor package” in the present application.

As shown in FIG. 2, drain **222** of control FET **220** is attached to die side **208** of conductive carrier section **210b**, and source **234** of sync FET **230** is attached to die side **208** of conductive carrier section **210d**. As further shown in FIG. 2, conductive carrier section **210a** includes conductive carrier buildup region **221a**, conductive carrier section **210c** is attached to gate **236** of sync FET **230**, and conductive carrier section **210e** includes conductive carrier buildup region **221e**. In addition, semiconductor package **201** includes electrically conductive die attach material **219**, patterned dielectric **240**, and insulator layer **250** providing surface **252**.

Also included as part of semiconductor package **201** are drain contact **223** provided by conductive carrier section **210b**, source contact **235** provided by conductive carrier section **210d**, gate contacts **227** and **237** provided by respective conductive carrier sections **210a** and **210c**, and switch node contact **229** provided by conductive carrier section **210e**. Conductive carrier section **210e** is also referred to as a switch node section of the conductive carrier. It is noted that in addition to providing drain contact **223**, conductive carrier section **210b** is configured to sink heat produced by control FET **220** into mounting surface **290**. Moreover, in addition to providing source contact **235**, conductive carrier section **210d** is configured to sink heat produced by sync FET **230** into mounting surface **290**. It is further noted that conductive carrier section **210e** is configured to provide switch node contact **229**, as well as to provide integrated heat spreading functionality for dissipation of heat generated by control and sync FETs **220** and **230**. In general, conductive carrier sections **210a**, **210b**, **210c**, **210d**, and **210e** provide electrical contacts as well as integrated heat spreading by sinking heat produced by control FET **220** and sync FET **230** into mounting surface **290**.

Semiconductor package **201** corresponds in general to power switching stage **101** in FIG. 1. In addition, control FET **220** having drain **222**, source **224**, and gate **226**, and sync FET **230** having drain **232**, source **234**, and gate **236**, correspond in general to control switch **120** having drain **122**, source **124**, and gate **126**, and sync switch **130** having drain **132**, source

5

134, and gate 136, respectively, in FIG. 1. Moreover, switch node contact 229, in FIG. 2, corresponds to switch node 129, in FIG. 1.

The features of semiconductor package 201 will be described in greater detail by reference to FIG. 3, and FIGS. 4A, 4B, 4C, 4D, 4E, and 4F (hereinafter "FIGS. 4A-4F"). However, it is noted in reference to FIG. 2 that the electrical connection between source 224 of control FET 220 and drain 232 of sync FET 230 is established in the absence of a conductive clip or other feature implemented solely or primarily as an electrical connector. Instead, according to the implementation shown in FIG. 2, the electrical connection between source 224 and drain 232 establishing switch node contact 229 is advantageously provided by conductive carrier section 210e, which includes conductive buildup region 221e. As a result, the packaging solution of FIG. 2 provides a robust, low resistance, and low parasitic connection for providing switch node contact 229. Moreover, the inventive concepts disclosed by the packaging solution represented in FIG. 2 can be extended to enable the fabrication of high density MCM packages, with reduced parasitics and improved thermal performance.

Referring to FIG. 3, FIG. 3 shows flowchart 300 presenting an exemplary method for fabricating a semiconductor package according to one implementation of the present disclosure. It is noted that the method described by flowchart 300 is performed on a portion of a conductive carrier structure, which may be a semiconductor package lead frame, or may take the form of a conductive sheet or plate, for example.

With respect to FIGS. 4A-4F, structures 410 through 415 shown respectively in those figures illustrate the result of performing the method of flowchart 300 according to one implementation of the present disclosure. For example, FIG. 4A represents non-contiguous, multi-section conductive carrier 410 including conductive carrier sections 410a, 410b, 410c, 410d, and 410e (hereinafter "conductive carrier sections 410a-410e") having die side 408 and opposite I/O side 418 (action 310), structure 411 shows non-contiguous, multi-section conductive carrier 410 after attachment to a control FET and a sync FET (action 311), structure 412 shows structure 411 after the formation of a dielectric layer (action 312), and so forth. It is noted that non-contiguous, multi-section conductive carrier 410 including conductive carrier sections 410a-410e, in FIGS. 4A through 4F, corresponds to conductive carrier 210 including conductive carrier sections 210a-210e, in FIG. 2.

Referring to flowchart 300, in FIG. 3, in combination with FIG. 4A, flowchart 300 begins with fabricating and/or providing a non-contiguous, multi-section conductive carrier 410 including conductive carrier sections 410a-410e and having die side 408 and opposite I/O side 418 (action 310). As shown in FIG. 4A, non-contiguous, multi-section conductive carrier 410 is represented as a pre-patterned conductive sheet or plate having die side 408, I/O side 418, and gaps 409a, 409b, 409c, and 409d (hereinafter "gaps 409a-409d") pre-patterned between respective conductive carrier sections 410a-410e and extending through the entire thickness of the conductive carrier between die side 408 to I/O side 418.

It is noted that conductive carrier sections 410a-410e are shown as connected by dashed lines 416 to indicate that gaps 409a-409d may be visible in FIGS. 4A-4F due to the cross-sectional perspective viewed in those figures, but do not extend through conductive carrier 410 in a direction perpendicular to the plane of the page of FIGS. 4A-4F. Thus non-contiguous, multi-section conductive carrier 410 may be made from a lead frame that is fully patterned to provide conductive carrier sections 410a-410e. Fully patterned con-

6

ductive carrier 410 may be formed of any conductive material having a suitably low electrical resistance. Examples of materials from which fully patterned, non-contiguous, multi-section conductive carrier 410 may be formed include copper (Cu), aluminum (Al), or a conductive alloy. In one implementation, as noted above, fully patterned conductive carrier 410 may be implemented using a semiconductor package lead frame.

Although the present exemplary implementation shows non-contiguous, multi-section conductive carrier 410 as including gaps 409a-409d, in other implementations, non-contiguous, multi-section conductive carrier 410 may have more, or fewer, gaps than gaps 409a-409d. Moreover, although not shown in the present figures, in some implementations, non-contiguous, multi-section conductive carrier 410 may include a barrier metal layer formed on one or both of die side 408 and I/O side 418. Such a barrier metal layer may be formed of nickel-gold (NiAu) or nickel-palladium-gold (NiPdAu), for example. In some implementations, such a barrier metal layer may serve as an etching mask during patterning of non-contiguous, multi-section conductive carrier 410. Thereafter, such a barrier metal layer can provide a solderable surface at one or both of die side 408 and I/O side 418 of non-contiguous, multi-section conductive carrier 410.

Moving to structure 411 in FIG. 4B with ongoing reference to FIG. 3, flowchart 300 continues with attaching control FET 420 (Q_1) and sync FET 430 (Q_2) to non-contiguous, multi-section conductive carrier 410 (action 311). Control FET 420 includes drain 422, source 424, and gate 426, while sync FET 430 includes drain 432, source 434, and gate 436. As shown in FIG. 4B, control FET 420 and sync FET 430 are attached to die side 408 of non-contiguous, multi-section conductive carrier 410 by electrically conductive die attach material 419.

Electrically conductive die attach material 419 may be any suitable substance, such as a conductive epoxy, solder, a conductive sintered material, or a diffusion bonded material, formed to a thickness of at least 10 μm , for example. Control FET 420 and sync FET 430 are shown as power FETs having a vertical topology. That is to say, source 424 and gate 426 are situated on the same side of control FET 420, while drain 422 is situated on an opposite side of control FET 420. Similarly, source 434 and gate 436 are situated on the same side of sync FET 430, while drain 432 is situated on an opposite side of sync FET 430.

In one implementation, respective control and sync FETs 420 and 430 may take the form of group IV material based vertical FETs, such as silicon vertical MOSFETs for example. However, in other implementations, respective control and sync FETs 420 and 430 may take the form of group III-V based power FETs, such as GaN or other III-Nitride based FETs.

It is noted that control FET 420 and sync FET 430 are flipped relative to each other. That is to say, control FET 420 is disposed on non-contiguous, multi-section conductive carrier 410 in a "face up" orientation in which drain 422 is attached to die side 408 of conductive carrier section 410b, while sync FET 430 is oriented "face down" such that gate 436 and source 434 are attached to die side 408 of respective conductive carrier sections 410c and 410d. Moreover, and as shown in FIG. 4B, sync FET 430 is disposed over gap 409c such that gap 409c is situated between the attachment of source 434 to die side 408 of conductive carrier section 410d and the attachment of gate 436 to die side 408 of conductive carrier section 410c. Control FET 420, sync FET 430, and electrically conductive die attach material 419 correspond respectively to control FET 220, sync FET 230, and electrically conductive die attach material 219, in FIG. 2.

As shown by structure **412** in FIG. 4C, flowchart **300** continues with forming dielectric layer **438** over non-contiguous, multi-section conductive carrier **410**, control FET **420**, and sync FET **430** (action **312**). As shown in FIG. 4C, in one implementation, dielectric layer **438** may be formed at die side **408** and I/O side **418** of non-contiguous, multi-section conductive carrier **410**. Formation of dielectric layer **438** may be performed through lamination of a pre-formed dielectric layer onto I/O side **418** and/or die side **408** of non-contiguous, multi-section conductive carrier **410**, control FET **420**, and sync FET **430**. Such a pre-formed dielectric layer may be cut or otherwise separated from a pre-formable dielectric material, for example an epoxy-phenolic or cyanate ester-epoxy build-up material or any other pre-formable dielectric utilized in laminate substrate technology. In one implementation, dielectric layer **438** may be formed of a B-stage polymeric material cured during lamination. As a result, and as shown in FIG. 4C, dielectric layer **438** can substantially fill gaps **409a-409d** appearing in FIGS. 4A and 4B.

Referring to FIG. 4D, flowchart **300** continues with patterning of dielectric layer **438** to form patterned dielectric **440** (action **313**). Patterned dielectric **440** may be produced so as to provide windows **442**. Patterning of dielectric layer **438** to form patterned dielectric **440** including windows **442** can be performed using any known technique, such as laser or mechanical drilling, for example. Patterned dielectric **440** includes windows **442** exposing portions of die side **408** of conductive carrier sections **410a** and **410e**, as well as exposing source **424** and gate **426** of control FET **420**, and drain **432** of sync FET **430**. In addition, according to the exemplary implementation shown in FIG. 4D, patterning of dielectric layer **438** to produce patterned dielectric **440** results in removal of dielectric material from I/O side **418** of non-contiguous, multi-section conductive carrier **410**. Patterned dielectric **440** corresponds to patterned dielectric **240**, in FIG. 2.

Moving to structure **414** in FIG. 4E, flowchart **300** continues with fabrication of one or more conductive layers over patterned dielectric **440**, and patterning of the conductive layer(s) to form conductive carrier buildup regions **421a** and **421e** (action **314**). The conductive layer(s) may be formed of Cu or Al, for example, or may be formed from a metal alloy, such as a metal alloy including Cu and Ni, for example. Such conductive layer or layers may be built up using any suitable technique, such as electrochemical deposition or an electrolytic plating process, for example. After build up, the conductive layer or layers are patterned to form conductive carrier buildup regions **421a** and **421e**. Conductive carrier buildup regions **421a** and **421e** correspond respectively to conductive carrier buildup regions **221a** and **221e**, in FIG. 2.

It is noted that control FET **420** and sync FET **430** are substantially embedded in non-contiguous, multi-section conductive carrier **410** including conductive carrier buildup regions **421a** and **421e**. As a result, conductive carrier section **410e** including conductive carrier buildup region **421e** can be utilized to electrically connect source **424** of control FET **420** to drain **432** of sync FET **430**. In addition, conductive carrier section **410e** can be used to provide switch node contact **429**. Moreover, patterned dielectric can **440** be utilized to provide electrical isolation of each of conductive carrier sections **410a-410e** from the others.

Continuing to structure **415** in FIG. 4F, flowchart **300** continues with forming insulator layer **450** over patterned dielectric **440** and conductive carrier buildup regions **421a** and **421e** (action **315**). Insulator layer **450** may be formed as a blanket layer of solder resist, for example, which provides surface

452. Insulator layer **450** providing surface **452** corresponds to insulator layer **250** providing surface **252**, in FIG. 2.

Although the implementations shown and described by reference to FIGS. 2, 3, and 4A-4F result in an MCM, such as semiconductor package **201**, in FIG. 2, configured to enclose power switching stage **101**, in FIG. 1, in some applications, it may be desirable to produce a semiconductor package corresponding to MCM **102**. An example implementation of such an MCM package is shown by FIG. 5. One of ordinary skill in the art will readily understand that the exemplary method outlined by flowchart **300**, in FIG. 3, can be suitably adapted to produce the exemplary MCM package structure shown in FIG. 5.

FIG. 5 shows a cross-sectional view of semiconductor package **502** attached to mounting surface **590**, such as a PCB for example, by solder bodies **592**. Semiconductor package **502** includes fully patterned or multi-section conductive carrier **510** having die side **508** and opposite I/O side **518**, and including conductive carrier sections **510a**, **510b**, **510c**, **510d**, **510e**, **510f**, and **510g**. As shown in FIG. 5, the fully patterned or multi-section conductive carrier **510** is a non-contiguous conductive carrier, and is made up of patterned and disjointed sections that are housed within semiconductor package **502**, and that are in electrical communication only through mounting surface **590**. The non-contiguous, fully patterned or multi-section conductive carrier **510** is also referred to simply as a “conductive carrier” in the present application.

Semiconductor package **502** further includes control FET **520** (Q_1) having drain **522**, source **524**, and gate **526**, as well as sync FET **530** (Q_2) having drain **532**, source **534**, and gate **536**. Control FET **520** and sync FET **530** are specific examples of power transistors used for illustrative purposes in the present application. However, it is manifest that other types of power transistors can be used as well without departing from the scope of the present inventive concepts. Thus, control FET **520** may be referred to as control transistor and sync FET **530** may be referred to as sync transistor in the present application. Source, drain, and gate of either control FET and/or sync FET may be referred to as a transistor terminal. A control transistor terminal may refer to source, drain, or gate of the control transistor, i.e. control FET **520** in the present example. Likewise, a sync transistor terminal may refer to source, drain, or gate of the sync transistor, i.e. sync FET **530** in the present example. Moreover, semiconductor package **502** may be referred to as a “power semiconductor package” in the present application.

As shown in FIG. 5, drain **522** of control FET **520** is attached to die side **508** of conductive carrier section **510b**, and source **534** of sync FET **530** is attached to die side **508** of conductive carrier section **510d**. Semiconductor package **502** also includes driver IC **594** for driving at least one of control FET **520** and sync FET **530**. In addition, semiconductor package **502** includes electrically conductive die attach material **519**, patterned dielectric **540**, and insulator layer **550** providing surface **552**.

Also included as part of semiconductor package **502** are drain contact **523** of control FET **520**, source contact, **535** of sync FET **530**, gate contacts **527** and **537**, switch node contact **529**, I/O contacts **596a** and **596b** of driver IC **594**, and die attach material **593** for attaching driver IC **594** to conductive carrier section **510f**. It is noted that, depending on the desired implementation, die attach material **593** may be an electrically conductive die attach material or a dielectric die attach material.

Conductive carrier section **510b**, control FET **520**, conductive carrier section **510d**, sync FET **530**, conductive carrier sections **510a**, **510c**, and **510e**, and electrically conductive die

attach material **519** correspond respectively to conductive carrier section **210b**, control FET **220**, conductive carrier section **210d**, sync FET **230**, conductive carrier sections **210a**, **210c**, and **210e**, and electrically conductive die attach material **219**, in FIG. 2. In addition, patterned dielectric **540**, contacts **523**, **527**, **529**, **535**, and **537**, and insulator layer **550**, in FIG. 5, correspond respectively to patterned dielectric **240**, contacts **223**, **227**, **229**, **235**, and **237**, and insulator layer **250**, in FIG. 2. Moreover, it is noted that semiconductor package **502** including driver IC **594**, in FIG. 5, corresponds in general to MCM **102** including driver IC **194**, in FIG. 1.

According to the implementation shown in FIG. 5, conductive carrier section **510e** advantageously provides switch node contact **529** and thereby establishes the electrical connection between source **524** of control FET **520** and drain **532** of sync FET **530**. Conductive carrier section **510e** is also referred to as a switch node section of the conductive carrier. Patterned dielectric **540** can be used to protect driver IC **594** from switching noise that may be present in conductive carrier section **510b**, conductive carrier section **510d**, and conductive carrier sections **510a**, **510c**, and **510e** by electrically isolating those conductive carrier sections from conductive carrier sections **510f** and **510g** to which driver IC **594** is connected. In addition, patterned dielectric **540** can be used to electrically isolate conductive carrier sections **510a**, **510b**, **510c**, **510d**, and **510e** from one another. Moreover, in addition to providing drain contact **523**, gate contacts **527** and **537**, source contact **535**, switch node contact **529**, and I/O contacts **596a** and **596b**, respective conductive carrier sections **510b**, **510a**, **510c**, **510d**, **510e**, **510f**, and **510g** provide integrated heat spreading by sinking heat produced by control FET **520**, sync FET **530**, and control IC **594** into mounting surface **590**.

Thus, embedding a power switching stage of a power converter in a conductive carrier utilized as a structural support in a semiconductor package advantageously enables a highly compact semiconductor package design, while concurrently providing thermal protection. In addition, by embedding the power switching stage in the conductive carrier so as to utilize the conductive carrier to provide a switch node coupling a control switch to a sync switch, the present application enables further reductions in package size. For example, a package height, or thickness, resulting from the implementations disclosed in the present application may be less than approximately 0.5 mm, such as a package height or thickness of approximately 0.45 mm. Furthermore, use of the conductive carrier to provide the switch node advantageously enables omission of a conductive clip, or any other feature implemented solely or primarily as a switch node electrical connector, from the semiconductor package.

From the above description it is manifest that various techniques can be used for implementing the concepts described in the present application without departing from the scope of those concepts. Moreover, while the concepts have been described with specific reference to certain implementations, a person of ordinary skill in the art would recognize that changes can be made in form and detail without departing from the scope of those concepts. As such, the described implementations are to be considered in all respects as illustrative and not restrictive. It should also be understood that the present application is not limited to the particular implementations described herein, but many rearrangements, modifications, and substitutions are possible without departing from the scope of the present disclosure.

The invention claimed is:

1. A power semiconductor package comprising:
 - a non-contiguous, multi-section conductive carrier;
 - a control transistor with a control transistor terminal coupled to a first section of said multi-section conductive carrier;
 - a sync transistor with a sync transistor terminal coupled to a second section of said multi-section conductive carrier;
 - said first and second sections of said multi-section conductive carrier sinking heat generated by said control and sync transistors;
 - said first and second sections of said multi-section conductive carrier being electrically connected only through a mounting surface attached to said power semiconductor package.
2. The power semiconductor package of claim 1, wherein said control transistor and said sync transistor form a power switching stage of a voltage converter.
3. The power semiconductor package of claim 1, wherein said multi-section conductive carrier is made from a patterned lead frame.
4. The power semiconductor package of claim 1, wherein said control transistor is a control FET, and said control transistor terminal is a drain of said control FET.
5. The power semiconductor package of claim 1, wherein said control transistor is a control FET, and said control transistor terminal is a source of said control FET.
6. The power semiconductor package of claim 1, wherein said sync transistor is a sync FET, and said sync transistor terminal is a drain of said sync FET.
7. The power semiconductor package of claim 1, wherein said sync transistor is a sync FET, and said sync transistor terminal is a source of said sync FET.
8. The power semiconductor package of claim 1, wherein said control transistor is a control FET, and said sync transistor is a sync FET, and wherein a source of said control FET is coupled to a drain of said sync FET through a switch node section of said multi-section conductive carrier.
9. The power semiconductor package of claim 1, further comprising a patterned dielectric situated between a plurality of sections of said multi-section conductive carrier.
10. The power semiconductor package of claim 1, further comprising an insulator layer overlying said multi-section conductive carrier.
11. The power semiconductor package of claim 1, wherein said mounting surface is a printed circuit board (PCB).
12. The power semiconductor package of claim 1, wherein said power semiconductor package is attached to said mounting surface by solder bodies.
13. A method for fabricating a power semiconductor package comprising:
 - providing a non-contiguous, multi-section conductive carrier;
 - attaching a control FET and a sync FET to said multi-section conductive carrier;
 - forming a dielectric layer over said multi-section conductive carrier and said control FET and sync FET;
 - patterning said dielectric layer to form a patterned dielectric situated between a plurality of sections of said multi-section conductive carrier;
 - fabricating conductive layers of said multi-section conductive carrier over said patterned dielectric and said control FET and said sync FET.
14. The method of claim 13 further comprising forming an insulator layer after said fabricating said conductive layers.

11

15. The method of claim 13, wherein said control FET and said sync FET form a power switching stage of a voltage converter.

16. The method of claim 13, wherein said multi-section conductive carrier is made by patterning a lead frame.

17. A power semiconductor package comprising:

a non-contiguous, multi-section conductive carrier;

a control transistor with a control transistor terminal coupled to a first section of said multi-section conductive carrier;

a sync transistor with a sync transistor terminal coupled to a second section of said multi-section conductive carrier;

a driver IC coupled to a third section of said multi-section conductive carrier;

said first, second, and third sections of said multi-section conductive carrier sinking heat generated by said control and sync transistors;

12

said first, second, and third sections of said multi-section conductive carrier being electrically connected only through a mounting surface attached to said power semiconductor package.

18. The power semiconductor package of claim 17, wherein said control transistor and said sync transistor form a power switching stage of a voltage converter.

19. The power semiconductor package of claim 17, wherein said multi-section conductive carrier is made from a patterned lead frame.

20. The power semiconductor package of claim 17, wherein said control transistor is a control FET, and said sync transistor is a sync FET, and wherein a source of said control FET is coupled to a drain of said sync FET through a switch node section of said multi-section conductive carrier.
